

Lecture 2 - Git & Github

Programming for VR I

Patrick Mineault

Github

- ▶ You will learn things that you will immediately forget
- ▶ If you leave a trail, you don't have to memorize
- ▶ Github can be your super-memory
- ▶ The history of everything you've ever programmed

Source control

- ▶ Github hosts git repositories
- ▶ A repository: think of it as a filesystem with a history
- ▶ git is a source-control technology that was originally made by Linus Torvalds (who also wrote the Linux kernel)

Github as a lurker

- ▶ An almost magical cornucopia of things you can download
- ▶ Which things are “good to download”? Watch out for:
 - ▶ License
 - ▶ Language
 - ▶ Stars and forks
 - ▶ Last commit

Github as a contributor

- ▶ Exercise: let's sign up for Github!

Two workflows

- ▶ Clone a repo: make a local copy of a repo.
- ▶ Command line `git clone`
`https://github.com/patrickmineault/programming-course.g`
- ▶ Try it!
- ▶ Q: can't I just download a zip file instead? Yes!

Create a repo and put stuff in it

- ▶ Create a repo, add stuff to it, and share it with the world.
- ▶ Let's create a repo on Github called `hello-world-python`
- ▶ Clone the repo
- ▶ Create a new file in the directory: `helloworld.py`
- ▶ Write our hello world example in there
- ▶ Commit it and push it

Key commands

- ▶ `git status`: What is the status of my repo?

```
$ git status
```

```
On branch master
```

```
Initial commit
```

```
Untracked files:
```

```
(use "git add <file>..." to include in what will be committed)
```

```
helloworld.py
```

```
nothing added to commit but untracked files present (use "git add" to track)
```

Key commands

- ▶ `git add myfile.ext`: Add a file to be committed. You need to add uncommitted files (new files and modified) before you can commit them.

```
git add helloworld.py
```

```
$ git status
```

```
On branch master
```

```
Initial commit
```

```
Changes to be committed:
```

```
(use "git rm --cached <file>..." to unstage)
```

```
new file:   helloworld.py
```

Key commands

- ▶ `git commit -m "My message":` commit *locally*

```
$ git commit -m "Life is fun"
```

```
[master (root-commit) 94583f3] Life is fun
```

```
1 file changed, 1 insertion(+)
```

```
create mode 100644 helloworld.py
```

- ▶ The message should tell, what this commit is, e.g. “added confobulator feature”.
- ▶ Now you have a commit.
- ▶ Now it's time to upload to Github.

Key commands

- ▶ `git push`: push the current branch to the remote (Github).

Summary

- ▶ Three commands:
- ▶ `git add`
- ▶ `git commit -m "message"`
- ▶ `git push`
- ▶ Commit often, push often (e.g. once a class)
- ▶ When in doubt, search for “git cheat sheet”

Context about how programmers use git and github

- ▶ Programmers often like to work on different features at the same time - each branch can be its own feature. We're just going to work on the master branch, which is the default one.

```
$ git branch
```

```
* master
```

- ▶ You can fork other people's code and then merge it back.
- ▶ git has a lot of tools for managing multiple versions of the same code simultaneously. We'll go with a very linear workflow, but you can use a very nonlinear method (think of the plot of Back to the Future 2)
- ▶ By having a complete record of what happened, when something goes very wrong, you can figure out what went wrong and why.

Exercise

- ▶ Create a repo for the class.
